## Abstract

In the past forty years in Japan and Taiwan, many thermal explosions have been caused by methyl ethyl ketone peroxide (MEKPO) under the influence of external fire and others. Thermograms of commercialized MEKPO dimers were first screened by Differential Scanning Calorimetry (DSC) to determine the heat of decomposition and exothermic onset temperature. Thermal runaway phenomena were then thoroughly investigated by Vent Sizing Package2 (VSP2). Data of thermokinetics and hazard behaviors were used for hazard analysis of MEKPO thermal explosions.

The onset temperatures of MEKPO monomer, which was prepared by the reaction of methyl ethyl ketone (MEK) and  $H_2O_2$ , were determined to be at about 40 °C, showing extremely dangerous while operating in hot ambient conditions, which is the first finding in literature. The novel finding shows that two peaks on the thermograms that indicate the MEKPO thermal runaway is a complicated reaction mechanism,

requiring further study for detailed thermal hazard investigation in the future.

Instead of normal one reaction peak from the adiabatic calorimeter, two exothermic peaks on the DSC thermograms is another novel finding among literatures. It was found that the reaction order of 1<sup>st</sup> peak of MEKPO dimer decomposition by isothermal analysis was 1. The Arrhenius parameters were calculated to be  $E_a$  (kcal mol<sup>-1</sup>) = 27.0 and  $\ln A$  (s<sup>-1</sup>) = 29, with reproducible confirmation. The reaction order of the 2<sup>nd</sup> peak of MEKPO dimer decomposition was 0.3 by DSC, showing the Arrhenius parameters of  $E_a$  (kcal mol<sup>-1</sup>) = 27.5 and  $\ln A$  (s<sup>-1</sup>) = 23. By VSP2 the Arrhenius parameters were determined as  $\ln A$  (s<sup>-1</sup>) = 20.7,  $E_a$  (kcal mol<sup>-1</sup>) = 20.3, and  $n = 1$ , respectively. Preventative measures can be established by these basic parameters so that the pro-active disaster prevention program can be practically achieved.

Keywords: methyl ethyl ketone peroxide, Differential Scanning Calorimetry, Vent Sizing Package2 (VSP2), thermal runaway, Arrhenius parameters.

## Introduction

Many thermal explosions caused by methyl ethyl ketone peroxide (MEKPO) under the influence of external fire have occurred in Japan and Taiwan in the past forty years, as shown in Tables 1 and 2 (Duh, 1998). In Taiwan, one of the worst accidents was the Yung-Hsin plant explosion occurred in 1996. The initial fire was due to out of control of oxidation reaction in process site, which was then spread to the tank yard. The fire-induced thermal explosion killed 10 and injured 47 people during the fire fighting. In Tokyo, 3,600 kg (8,000 lb) of MEKPO exploded under the influence of a fire in 1964, killing 19 and wounding 114 people, along with the damage of 1.25 U.S. million dollars (AIChE, 1995).

MEKPO, which is a common name of peroxides produced by reacting methyl ethyl ketone (MEK) with hydrogen peroxide ( $H_2O_2$ ), is widely used in industry as a radical catalyst source for initiating and cross-linking polymerization. In practice, commercial MEKPO is not a single compound but with isomers. Theoretically, seven different types of MEKPO might be co-existed (Milas, 1959), but only monomer and dimer forms have prevailed (OSHA, 1989). Due to the complex molecular structure, some of them possess higher potential of reactive hazard and thermal sensitivity than others. In NFPA 43B, the property of MEKPO has been recognized as class III and IV shown in Table 3 (NFPA 43B, 1999). To comply with the U.S. Department of Transportation (DOT) shipping regulations, the MEKPO should be diluted to weight percent concentration of 60 wt % or less with dimethylphthalate (DMP) as shown in Table 4 (DOT, 1990). The largest quantity of a commercial package was limited to be 5 gallons by NFPA 43B.

The decomposition of MEKPO is extremely complicated because of its radical-induced reaction mechanism. Objectively, this study was to investigate the

safety margins for processing and a acquire proper knowledge to identify the hazard for operating MEKPO and validate thermal hazard characteristics of MEKPO dimer under runaway conditions. Therefore, in this study, Differential Scanning Calorimetry (DSC) and Vent Sizing Package2 (VSP2) were used, along with thermal analysis techniques to measure thermokinetics data, specifically for runaway assessment. Thermograms of commercialized MEKPO were first screened by DSC to determine the heat of decomposition and exothermic onset temperature. Thermal runaway phenomena were then thoroughly investigated under adiabatic environment by VSP2. Data of thermokinetics and hazard potentials were used for hazard analysis of MEKPO thermal explosion. The resulted temperature-time profile and self-heat rate, based on the thermal runaway theory of Townsend and Tou, were manipulated to determine parameters in the exothermic decomposition reaction kinetics (Barton, 1997; Townsend, 1980).

## Experiment

**Samples.** 32wt % MEKPO was purchased directly from the Fluka Co., then stored in a 4 °C refrigerator. As mentioned above, DMP was used as the diluent solvent in preparing various MEKPO samples. On the other hand, the MEKPO monomer was synthesized by reacting MEK with H<sub>2</sub>O<sub>2</sub>. Two typical forms of MEKPO are shown in Figure 1 (OSHA, 1989).

**DSC (Differential Scanning Calorimetry).** Temperature-programmed screening and isothermal experiments were performed on a Mettler TA8000 system coupled with a DSC821<sup>e</sup> measuring cell that can withstand relatively high pressure to approximately 100 bar. Star<sup>e</sup> software was used for obtaining thermograms and isothermal traces (Mettler, 1998). For better thermal equilibrium purposes, the scanning rate chosen for the temperature-programmed ramp was 4 °Cmin<sup>-1</sup> (Hou, 2001).

**VSP2 (Vent Sizing Package2).** A PC-controlled adiabatic calorimeter system, the Vent Sizing Package2 (VSP2) manufactured by Fauske Associates, Inc. (FAI, 1996), was utilized to measure the thermokinetic and thermal hazard data such as temperature and pressure traces with respect to time. The low heat capacity of the cell ensures that essentially all the reaction heat released remains within the test sample. Thermokinetics and pressure behaviors in the small test cell (112 ml) can therefore be extrapolated directly to the process scale due to the low thermal inertia of about 1.05 to 1.2 (Wang, 2001). The worst credible case can be also simulated under adiabatic, cooling failure or external fire conditions, to name a few.

## Results and Discussion

**Thermal Analysis by DSC.** In general, a DSC-programmed scanning can readily acquire the onset temperature and heat of decomposition of MEKPO dimer. Figure 2 shows the typical temperature and heat flow curves for the thermal decomposition of 4 wt %, 8 wt %, 16 wt % and 32 wt % MEKPO/DMP solution, respectively. The thermal decomposition hazards of MEKPO with different concentrations can be characterized by using a non-isothermal method. The heat of MEKPO thermal decomposition with different concentrations was measured, resulting in good agreement among these tests. According to the results, the onset temperatures were determined at about 110 °C. The heat of decomposition was measured to be  $(3,300 \pm 250)$  J per gram of MEKPO dimer (100 wt %). Data of thermal analyses are listed in Table 5. Results of physical data including heat of decomposition, initially exothermic onset temperature, heat flow, and curves of thermograms are suitable for exhibiting the strength of reactivity as well as thermal hazards of MEKPO dimer. The novel finding shows that two peaks on the thermograms indicate that the MEKPO dimer thermal runaway is a complicated reaction mechanism, requiring further study for detailed thermal hazard investigation in the future (Shu, 2001).

Apparently, the dynamic method described above does not direct to a full understanding of the complex decomposition mechanism of MEKPO. Contrasting to the dynamic method, isothermal analysis does eliminate the thermal lag effect and maintain better thermal equilibrium than using n-th order model. The isothermal tests were conducted between 100 °C and 130 °C with a series of different concentrations followed by dynamic test with scanning rate in  $4 \text{ }^\circ\text{Cmin}^{-1}$  to determine reaction order of MEKPO, as shown in Table 6.

The onset temperatures of MEKPO monomer prepared from reaction of MEK

and  $\text{H}_2\text{O}_2$  were determined to be at about  $40\text{ }^\circ\text{C}$  which is the first finding in literature. It will be more hazardous and unstable because of the lower temperature exothermic phenomenon shown in Figure 3, in which three sample weights of 2.2 mg, 2.4 mg and 2.5 mg illustrate the very close and consistent results. The monomer type has illustrated higher heat flow at lower temperature, higher heat of decomposition than the dimer one, as shown in Figure 4. Owing to the different molecular structure compared to the dimer, onset temperature of MEKPO monomer measured in DSC is even as low as  $40\text{ }^\circ\text{C}$ , demonstrated an extremely high degree of thermal hazard while being handled under hot ambient conditions.

**Thermal Analysis by VSP2.** The characteristic curves of time versus temperature of MEKPO dimer are recorded in Figure 5. The main reason, which shows the maximum temperature of 45 ml MEKPO dimer exceeds the 60 ml, may be ascribed to the fact that the depth of thermocouple is located at the interface between the liquid phase and gas phase of the test cell. In view of the limitation of VSP2 with higher concentration of MEKPO dimer, VSP2 experimental data of 10 wt % MEKPO dimer are summarized in Table 7. The onset temperature of 10 wt % MEKPO was chosen to be the exothermic temperature which reaches the sensitivity of the VSP2 calorimeter. Defining the temperature with self-heat rate of  $0.1\text{ }^\circ\text{C min}^{-1}$  as the initial temperature, the onset temperature of 10 wt % MEKPO is  $88\text{ }^\circ\text{C}$  with the thermal inertia ( $\Phi$ ) of 1.16. The only one peak appeared in VSP2 was due to the first exothermal peak as heat being accumulated to exceed the onset temperature of second exothermal peak ( $T_{01} + \Delta T_{AD} > T_{02}$ ). Figure 6 indicates the self-heat rate vs. temperature where the maximum self-heat rate is  $21.8\text{ }^\circ\text{Cmin}^{-1}$ . The major decomposition products of MEKPO dimer are carbon dioxide, water, acetic acid, formic acid and methyl ethyl ketone (AKZO, 1996).

The maximum temperature of 10 wt % MEKPO dimer during the adiabatic runaway was determined to be 238 °C, which explained the MEKPO is a highly hazardous material. The released gas products were  $2.87 \times 10^{-2}$  moles per gram MEKPO, which can be correlated to the severity of thermal explosion caused by heat source, such as an external fire.

**Kinetics Analysis by DSC.** Isothermal analysis compared with Borchardt and Daniel method were used in kinetics analysis by DSC calorimetry (Borchardt, 1956). Based on the isothermal measurement results, the Arrhenius plot of  $\ln k$  versus  $1/T$  with different temperatures is a straight line, providing the activation energy for MEKPO dimer decomposition. The reaction order of 1<sup>st</sup> peak of MEKPO dimer decomposition by isothermal analysis was determined to be 1<sup>st</sup> order. The Arrhenius parameters were calculated to be  $E_a$  (kcal mol<sup>-1</sup>) = 27.0 and  $\ln A$  (s<sup>-1</sup>) = 29. In addition, the second peak was checked with standard decomposition reaction of 20 wt % di-tert-butyl peroxide (DTBP) in toluene, then applied to MEKPO dimer studies. The Arrhenius parameters of DTBP with first order decomposition were determined to be  $E_a$  (kJmol<sup>-1</sup>) = 157 and  $\ln A$  (s<sup>-1</sup>) = 36.0 in excellent accordance with previous studies (Duh, 1997; Shaw, 1968). The reaction order of the 2<sup>nd</sup> peak of MEKPO decomposition was 0.3 by DSC, indicating the Arrhenius parameters of  $E_a$  (kcal mol<sup>-1</sup>) = 27.5 and  $\ln A$  (s<sup>-1</sup>) = 23, as shown in Table 8.

**Kinetics Analysis by VSP2.** Adiabatic decomposition kinetics of 10 wt % MEKPO can be deduced from the relationship between temperature and time or via the self-heat rate (Townsend, 1980). A pseudo zero-order rate constant ( $k^*$ ) for n-th order exothermic decomposition reaction can be calculated from the observed self-heat rate at specific temperature (T).

$$k^* = C_0^{n-1} k = \frac{m_T}{\left(\frac{T_f - T}{\Delta T_{AD}}\right)^n \Delta T_{AD} C_0^{n-1}} \quad (1)$$

This can be related to the Arrhenius equation (Eq (2)):

$$\ln k^* = \ln C_0^{n-1} A - \frac{E_a}{R} \left(\frac{1}{T}\right) \quad (2)$$

As expected from experimental data, the plot of  $\ln k^*$  versus  $1/T$  is a straight line which is assumed that the order of reaction is chosen correctly in Figure 7. The Arrhenius parameters were determined as  $\ln A \text{ (s}^{-1}\text{)} = 20.7$ ,  $E_a \text{ (kcal mol}^{-1}\text{)} = 20.3$ , and  $n = 1$ , respectively. Based on the methodology of Design Institute for Emergency Relief system (DIERS) of AIChE, these values are very helpful while designing the pressure relief system specifically under runaway reaction during processing, transportation, and storage periods.

Table 9 summarizes the overall Arrhenius parameters measured with the VSP2 and by the other studies (Lee, 1969; Stull, 1977; ITRI, 1994).

## **Conclusions**

This study demonstrates that the application of calorimetry techniques for investigating the exothermic decomposition of MEKPO is a promising way of generating the data necessary for reaction hazard analysis which can, in turn, identify the rule in safer shipping and handling of MEKPO reaction synthesis.

MEKPO is a common name used in the chemical industries, however the characteristics of thermal decomposition behaviors were quite different. From this study, it concludes that monomer type MEKPO is the most hazardous one among the compound series owing to the lower decomposition temperature. High heat-releasing rate is ascribed to the kinetics during decomposition. Severe consequence caused by MEKPO thermal explosion could be explained by the features of large quantity of heat of decomposition, non-condensed gas products and specific rate constant.

The experimental data from thermal calorimetry can provide fundamental safety characteristics and can be utilized to pro-actively prevent the occurrence of thermal runaway reactions.

## Nomenclature

$\Delta H$	heat of reaction, $\text{kJ mol}^{-1}$
$\Delta H_d$	heat of decomposition, $\text{kJ mol}^{-1}$
$\Delta H_1$	heat of decomposition for first peak, $\text{kJ mol}^{-1}$
$\Delta H_2$	heat of decomposition for second peak, $\text{kJ mol}^{-1}$
$(dP/dt)_{\text{maj}}$	maximum pressure rise rate, $\text{psi min}^{-1}$
$(dT/dt)_{\text{max}}$	maximum self-heat rate, $^{\circ}\text{Cmin}^{-1}$
$dT/dt$	self-heat rate, $^{\circ}\text{Cmin}^{-1}$
$(dT/dt)_0$	self-heat rate at onset temperature, $^{\circ}\text{Cmin}^{-1}$
$E_a$	apparent activation energy, $\text{kJmole}^{-1}$
$k$	rate constant, $\text{sec}^{-1}\text{M}^{1-n}$
$\ln A$	fractional factor, $\text{s}^{-1}$
$m$	mass of reactant, g
$n$	reaction order, dimensionless
$P_{\text{max}}$	maximum pressure, psig
$R$	rate of reaction, $\text{Msec}^{-1}$
$T$	temperature, $^{\circ}\text{C}$
$t$	time, min
$T_0$	initial exothermic temperature, $^{\circ}\text{C}$
$T_{01}$	first peak of initial exothermic temperature, $^{\circ}\text{C}$
$T_{02}$	second peak of initial exothermic temperature, $^{\circ}\text{C}$
$T_f$	final temperature, $^{\circ}\text{C}$
$T_{\text{max}}$	maximum temperature, $^{\circ}\text{C}$
$\text{TMR}$	time to maximum rate, min
$V$	volume of reactant, ml

$\rho$

density of reactant,  $\text{g}^{-1}$
